# ON THE TRANSVERSALITY OF RESTRICTED LINEAR SYSTEMS

#### ANITA BUCKLEY - MARINA ZOMPATORI

In this paper we prove a generalization of the Transversality Lemma first proved by Hirschowitz [5] and later by Ciliberto and Miranda [1]. We plan to use this lemma to calculate the dimensions of linear systems of plane curves with homogeneous vanishing conditions, using a degeneration technique developed by Ciliberto and Miranda<sup>1</sup>.

### Introduction.

In order to study linear systems of plane curves of the type  $\mathcal{L}_d(m^n)$ , i.e. systems of plane curves of degree d going through n points in general position with multiplicity at least m at every point, it is often useful to consider degenerations of the plane itself, of the bundle  $\mathcal{O}(d)$  and of the position of the points. One possible approach is to degenerate the plane by blowing up general points on the central fiber of  $\mathbb{P}^2 \times \Delta$ , where  $\Delta$  is a disc centered at the origin as follows.

Consider  $V=\mathbb{P}^2\times \Delta$  and its projections  $p_1:V\to \Delta$  and  $p_2:V\to \mathbb{P}^2$ . Denote  $V_t=\mathbb{P}^2\times \{t\}$ . Consider n general points in the plane  $V_0$ 

We wish to thank the organizers of Pragmatic 2001 for sponsoring our stay in Catania, Rick Miranda and Ciro Ciliberto for introducing us to problems on linear systems and for many invaluable conversations. We would also like to thank Dan Abramovich, who suggested and explained the use of monodromy arguments in the proof of the transversality lemma, and Balázs Szendrői for corrections and comments.

and blow V up at these points. We get a new threefold X equipped with maps  $f: X \to V$ , and  $\pi = p_1 \circ f: X \to \Delta$ , which gives a flat family of surfaces over  $\Delta$ . If we denote by  $X_t$  the fiber of  $\pi$  over  $t \in \Delta$ , then for  $t \neq 0$ ,  $X_t$  is just a plane  $\mathbb{P}^2$ , whereas  $X_0$  consists of the proper transform of  $V_0$ , which we denote by Y, and of n copies of  $\mathbb{P}^2$ . The n disjoint copies of  $\mathbb{P}^2$  are the exceptional divisors and each of them intersects Y along an exceptional line. Using this degeneration with an appropriate degeneration of the line bundle  $\mathcal{O}(d)$ , we see then that the system we want to study is now obtained by glueing together curves from the different  $\mathbb{P}^2$ s and curves from Y.

To understand the dimension of the resulting system, which will be a specialization of  $\mathcal{L}_d(m^n)$ , we need to calculate the dimension of the intersection of linear systems on Y and the systems on the planes.

If we think about the vector spaces of polynomials whose projectivizations give the systems of curves described above, the problem becomes then finding the dimension of the intersection of a vector space W, which in our application corresponds to the restriction of curves on Y onto the exceptional lines, with a sum of vector spaces  $U_1 \oplus \ldots \oplus U_n$ , where each  $U_i$  is the restriction onto exceptional line  $E_i$  of the system on the corresponding  $\mathbb{P}^2$ . This intersection takes place in  $V_1 \oplus \ldots \oplus V_n$ , where the projectivization of each  $V_i$  is the linear system of divisors of some degree k on  $\mathbb{P}^1$ .

In our application, all the copies of  $\mathbb{P}^2$  in X, are obtained as exceptional divisors from blow-ups at points in general position. In this setting, monodromy considerations give us symmetry conditions on the space W, which, in a more general case, have to be assumed.

We need the notion of transversal intersection, which we now define.

**Definition 1.** Suppose  $V_1$ ,  $V_2$  are two subspaces of a vector space V. Then we say that  $V_1$  and  $V_2$  intersect transversally if either  $\dim(V_1 \cap V_2) = 0$  or  $\dim(V_1 \cap V_2) = \dim(V_1) + \dim(V_2) - \dim(V)$ .

Hirschowitz [5] and later Ciliberto and Miranda [1] proved the following result known as The Transversality Lemma.

**Proposition 2.** Let  $G = GL(2, \mathbb{C})$  be the automorphism group of  $\mathbb{C}^2$ . Let V be the vector space whose projectivization is the linear system of divisors of degree k on  $\mathbb{P}^1$ . Note that G acts naturally on V, and on linear subspaces of V of any dimension. Then for any two linear subspaces W and W of W there is an element  $G \in G$  such that W meets G transversally.

The purpose of this paper is to generalize the above result to an arbitrary number of vector spaces using an inductive argument.

Let  $V_i$ , for  $i=1,\ldots,n$  be isomorphic vector spaces whose projectivization is the linear system of divisors of degree k, and for each i let  $U_i$  be a subspace of  $V_i$ . The same group  $G=GL(2,\mathbb{C})$  is acting on every  $V_i$ . Consider a vector space W which is a subspace of  $V_1 \oplus \ldots \oplus V_n$  and let  $p_i: W \to V_i$  be the projection map to each component. The situation is shown in the following diagram of vector spaces:

Our aim is to find elements  $g_1, \ldots, g_n \in G$  such that W and  $g_1U_1 \oplus \ldots \oplus g_nU_n$  meet transversally in  $V_1 \oplus \ldots \oplus V_n$ . This will not be possible for general W,  $U_i$  and  $V_i$ . The result will hold if the vector spaces satisfy a *quasi-symmetric* condition which we now define.

**Definition 3.** The diagram (**a**) is <u>quasi-symmetric</u> if it satisfies the following two properties:

(a) if there exist an integer r,  $1 \le r < n$ , and elements  $g_1, \ldots, g_r$  in G such that

$$(p_1,\ldots,p_r)W\cap(g_1U_1\oplus\ldots\oplus g_rU_r)=\{0\}$$

then there exist  $g'_1, \ldots, g'_{r+1}$  in G such that

$$(p_1,\ldots,p_{r+1})W\cap(g_1'U_1\oplus\ldots\oplus g_{r+1}'U_{r+1})=\{0\}$$

as well;

(b) suppose that for  $1 \le r < n$ , there is an r-tuple of elements  $g_1, \ldots, g_r$  such that the intersection

$$(p_1,\ldots,p_r)W\cap(g_1U_1\oplus\ldots\oplus g_rU_r)$$

is transversal and nontrivial. Define

$$W' = (p_1, \ldots, p_r)^{-1}[(p_1, \ldots, p_r)W \cap (g_1U_1 \oplus \ldots \oplus g_rU_r)]$$

and assume that for some  $g_{r+1}$  the intersection

$$p_{r+1}W' \cap g_{r+1}U_{r+1} = \{0\}$$

then there exist  $g'_1, \ldots, g'_{r+1}$  in G such that

$$(p_1, \ldots, p_{r+1})W \cap (g_1'U_1 \oplus \ldots \oplus g_{r+1}'U_{r+1}) = \{0\}$$

## 1. Proof of Transversality Lemma for any n.

**Theorem 4.** If the diagram ( $\spadesuit$ ) satisfies the quasi-symmetric condition, then there exist elements  $g_1, \ldots, g_n \in G$  such that W and

$$g_1U_1\oplus\cdots\oplus g_nU_n$$

meet transversally in  $V_1 \oplus \ldots \oplus V_n$ .

The aim of this section is to prove the Theorem 4. We prove it using induction on n. The case n = 1 is given by the Proposition 2. Its proof can be found in [1] on page 199.

Assume that the statement holds for n-1. If

$$(p_1, \ldots p_{n-1})W \cap (g_1U_1 \oplus \ldots \oplus g_{n-1}U_{n-1}) = \{0\},\$$

then by condition (a) the intersection of

W with 
$$g_1'U_1 \oplus \ldots \oplus g_n'U_n$$
,

for some  $g'_1, \ldots, g'_n \in G$ , is also  $\{0\}$ . In this case we get transversal intersection. Next define

$$W_1 = (p_1, \ldots, p_{n-1})^{-1} [(p_1, \ldots, p_{n-1}) W \cap g_1 U_1 \oplus \ldots \oplus g_{n-1} U_{n-1}].$$

Note that  $W_1$  equals

$$W \cap (g_1 U_1 \oplus \ldots \oplus g_{n-1} U_{n-1} \oplus V_n) =$$
  
$$\{(v_1, \ldots, v_n) \in W \mid v_i \in g_i U_i \ \forall \ i = 1, \ldots, n-1\}.$$

Its dimension is given by the following formula,

$$\dim W_1 =$$

$$\dim(\ker(p_1,\ldots,p_{n-1})) + \dim((p_1,\ldots,p_{n-1})W \cap g_1U_1 \oplus \ldots \oplus g_{n-1}U_{n-1}).$$

By applying the Transversality Lemma for n=1, (Proposition 2), to  $p_n(W_1)$  and  $U_n$ , subspaces of  $V_n$ , we can find an element  $g_n \in G$  such that  $p_n(W_1)$  and  $g_nU_n$  meet transversally. Suppose they meet trivially, then by condition (b) there exist  $g'_1, \ldots, g'_n \in G$  such that

$$W \cap (g_1'U_1 \oplus \ldots \oplus g_n'U_n) = \{0\}.$$

So in the case  $p_n(W_1) \cap g_nU_n = \{0\}$ , we again get the desired transversality.

The only case we still need to analyze is when the above transversal intersections are non trivial.

Define

$$W_2 = (p_n|_{W_1})^{-1}(p_n(W_1) \cap g_nU_n)$$

which equals to  $W \cap (g_1U_1 \oplus \ldots \oplus g_nU_n)$ . Its dimension is given by the following expression,

(2) 
$$\dim W_2 = \dim \ker(p_n|_{W_1}) + \dim(p_n(W_1) \cap g_nU_n).$$

Observe also that  $\dim(W \cap (g_1U_1 \oplus \ldots \oplus g_nU_n)) = \dim W_2$ . By transversality in the case n = 1, having already examined the case of trivial intersection, we have

$$\dim(p_n(W_1) \cap g_n U_n) = \dim p_n(W_1) + \dim U_n - \dim V_n.$$

By formula (2), we get the following identity,

$$\dim(W_2) = \dim \ker(p_n|_{W_1}) + \dim(p_n(W_1)) + \dim(U_n) - \dim(V_n).$$

Now note that dim  $(\ker(p_n|_{W_1})) + \dim(p_n(W_1)) = \dim W_1$ . Therefore dim  $W_2 = \dim W_1 + \dim U_n - \dim V_n$ . By formula (1), we derive the following expression for dim  $W_2$ ,

$$\dim W_2 = \dim \ker(p_1, \dots p_{n-1}) + \dim((p_1, \dots p_{n-1})(W) \cap g_1 U_1 \oplus \dots \oplus g_{n-1} U_{n-1}) + \dim U_n - \dim(V_n).$$

Since we have already considered the case

$$(p_1, \ldots p_{n-1})W \cap (g_1U_1 \oplus \ldots \oplus g_{n-1}U_{n-1}) = \{0\},\$$

we can now assume that this intersection is not zero and apply the transversality lemma in case n-1. This gives

(W) 
$$\dim \ker(p_1, \dots p_{n-1}) + \dim(p_1, \dots p_{n-1}) + \dim U_1 + \dots + \dim U_n - \dim V_1 - \dots - \dim V_n.$$

Finally,  $\dim \ker(p_1, \dots p_{n-1}) + \dim(p_1, \dots p_{n-1})(W)$  add up to  $\dim(W)$  and the expression above reduces to

$$\dim W + \dim U_1 + \ldots \dim U_n - \dim V_1 - \ldots - \dim V_n$$
.

We have  $\dim(W \cap (g_1U_1 \oplus \ldots \oplus g_nU_n)) = \dim W_2$  and is therefore equal to

$$\dim W + \dim U_1 + \ldots \dim U_n - \dim V_1 - \ldots - \dim V_n$$
.

This implies that the two spaces W and  $g_1U_1 \oplus \ldots \oplus g_nU_n$  intersect transversally in  $V_1 \oplus \ldots \oplus V_n$ , which completes the proof.

## 2. Application to systems of plane curves..

As we described in the Introduction and more precisely in [7], we need the generalized transversality lemma in order to study the dimension of linear systems of plane curves of some degree with base points of equal multiplicity.

By a degeneration of the plane and of the linear system itself, as explained in [7], we get the following diagram of vector spaces.

$$\mathbf{L}_{k}(m^{n_{2}}) \oplus \mathbf{L}_{k}(m^{n_{2}}) \oplus \cdots \oplus \mathbf{L}_{k}(m^{n_{2}})$$

$$\downarrow^{r_{1}} \qquad \qquad \downarrow^{r_{2}} \qquad \qquad \downarrow^{r_{n_{1}}}$$

$$\mathbf{L}_{d}(k^{n_{1}}) \xrightarrow{\rho_{Y}} H^{0}(\mathcal{O}_{E_{1}}(k)) \oplus H^{0}(\mathcal{O}_{E_{2}}(k)) \oplus \cdots \oplus H^{0}(\mathcal{O}_{E_{n_{1}}}(k)).$$

Here  $\mathbf{L}_k(m^{n_2})$  is the linear system of plane curves of degree k with  $n_2$  generic base points all of multiplicity m and similarly  $\mathbf{L}_d(k^{n_1})$  denotes the linear system of plane curves of degree d with  $n_1$  base points in general position all having the same multiplicity k.

This is how these systems arise in the application we are interested in: the environment we're in consists of the union of a variety Y, obtained as the proper transform of the plane blown up at  $n_1$  generic points, and  $n_1$  copies of the projective plane  $\mathbb{P}_i$ , obtained as exceptional divisors in our construction. Each  $\mathbb{P}_i$  intersects Y along a line  $E_i$ . We not only degenerate the plane but also the bundle  $\mathcal{O}_{\mathbb{P}^2}(d)$ , by pulling it back to the variety obtained by blowing up and twisting by  $\mathcal{O}(kY)$ . The system whose dimension we want to compute contains exactly the curves that are deformations of plane curves in  $\mathbf{L}_d(m^{n_1n_2})$ . It is given as a fibered product of the systems  $\mathbf{L}_k(m^{n_2})$  on  $\mathbf{P}_i$  and the system  $\mathbf{L}_d(k^{n_1})$  on Y. The restrictions of these systems to the lines  $E_i$  gives divisors of degree k on the line. In other words, the system is obtained by "pasting" together the system from Y and the systems from the planes  $\mathbf{P}_i$  along the lines  $E_i$ . Details about this construction, which is a degeneration technique introduced by C. Ciliberto and R. Miranda in order to study systems of plane curves, can be found in [7].

By restricting to exceptional lines  $E_i$  we therefore get the following diagram

on which we want to use the transversality lemma.

## 3. Systems of plane curves satisfy quasi-symmetric condition.

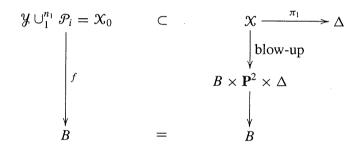

Our goal is to apply the transversality lemma to the above diagram. We need to show that it satisfies the quasi-symmetric condition.

Note that for a general number of points in  $\mathbf{P}^2$ , there exists no automorphism on  $\mathbf{P}^2$  permuting these points. In order to get the symmetric group action, we need to enlarge our ambient set-up and use monodromy.

Consider the product of  $n_1$  copies of the plane,  $\mathbf{P}^2 \times \ldots \times \mathbf{P}^2$ , and its subset  $D := \{(x_1, \ldots, x_{n_1}) \mid \exists 1 \leq i < j \leq n_1 \text{ such that } x_i = x_j\}$ . Then denote  $B = (\mathbf{P}^2 \times \ldots \times \mathbf{P}^2) \setminus D$ .

Next consider the product  $B \times \mathbf{P}^2 \times \Delta$ , where  $\Delta$  is a disc centered at the origin. Such product comes equipped with a projection to B which has sections  $\sigma_1, \ldots, \sigma_{n_1}$ .

We blow up  $B \times \mathbb{P}^2 \times \Delta$  along these sections and thus obtain the space  $\mathfrak{X}$ . Such space comes naturally with projection  $\pi_1 : \mathfrak{X} \to \Delta$ . Consider  $\mathfrak{X}_0 := \pi_1^{-1}(0)$ , a reducible scheme that consists of the exceptional subschemes  $\mathcal{P}_1, \ldots, \mathcal{P}_{n_1}$  and of  $\mathcal{Y}$ , which is the direct transform of  $B \times \mathbb{P}^2 \times \{0\}$ .

Also denote by  $\mathcal{E}_i$ , the bundle  $\mathcal{P}_i \cap \mathcal{Y}$ .

**Remark.** Note that the fiber over each  $b \in B$  is the same construction we describe in [7], where we just take  $\mathbb{P}^2 \times \Delta$  and blow it up at  $n_1$  points in the central fiber. In the same construction, we also need to degenerate the bundle  $\mathcal{O}_{\mathbb{P}^2}(d)$ , by pulling it back to the three-fold obtained by blowing up and twisting it with  $\mathcal{O}(Y)$ . We proceed in a similar way now in our more general situation.

Let  $\eta$  be the natural map  $\eta: \mathcal{X} \to \mathbb{P}^2$ . Let  $\mathcal{F}$  be the following sheaf on  $\mathcal{X}$ ,

$$\mathcal{F}=\eta^*\mathcal{O}_{\mathbb{P}^2}(d)\otimes\mathcal{O}_{\mathfrak{X}}(k\mathcal{Y}).$$

If we restrict  $\mathcal F$  to the central fiber  $\mathcal X_0$ , we obtain a sheaf  $\mathcal F(d,k)$  such that  $\mathcal F\mid_{\mathcal Y}=\mathcal O_{\mathcal Y}(d\eta^*L-\sum_{i=1}^{n_1}k\mathcal E_i)$  and  $\mathcal F\mid_{\mathcal P_i}=\mathcal O_{\mathcal P_i}(k)$ .

Denote by f the map from  $X_0$  to B and consider the following sheaves on B,

$$\mathcal{W} := f_* \mathcal{F}(d,k) \mid_{\mathcal{Y}}, \mathcal{U}_i := f_* \mathcal{F}(d,k) \mid_{\mathcal{P}_i} \text{ and } \mathcal{V}_i := f_* \mathcal{F}(d,k) \mid_{\mathcal{E}_i}$$

Our situation is now described by the following diagram of bundles over B,

$$\mathcal{U}_1 \oplus \mathcal{U}_2 \oplus \cdots \oplus \mathcal{U}_{n_1-1} \oplus \mathcal{U}_{n_1}$$

$$\downarrow^{r_1} \qquad \downarrow^{r_2} \qquad \qquad \downarrow^{r_{n_1}-1} \qquad \downarrow^{r_1}$$
 $\mathcal{W} \xrightarrow{r} \mathcal{V}_1 \oplus \mathcal{V}_2 \oplus \cdots \oplus \mathcal{V}_{n_1-1} \oplus \mathcal{V}_{n_1}$ 

where r,  $r_i$  are restrictions to  $\mathcal{E}_i$ .

The global sections of these sheaves over  $b \in B$  are,

$$W_b = H^0(Y_b, \mathcal{O}(d\eta^*L - \sum kE_{i,b})), \ V_{i,b} == H^0(E_{i,b}, \mathcal{O}_{\mathbb{P}^1(k)})$$

and

$$\mathcal{U}_{i,b} = H^0(P_{i,b}, \mathcal{O}_{\mathbb{P}^2}(k)),$$

where we also require that the sections in  $U_{i,b}$  vanish with multiplicity m at each of  $n_2$  generically chosen points.

Here  $Y_b$ ,  $E_{i,b}$  and  $\mathbb{P}_{i,b}$  are the fibers over  $b \in B$  of  $\mathcal{Y}$ ,  $\mathcal{E}_i$  and  $\mathcal{P}_i$  respectively. Note from the construction that  $Y_b$  is the proper transform of the plane blown up at  $n_1$  generic points, and  $\mathbb{P}_{i,b}$  is a projective plane which intersects  $Y_b$  along a projective line  $E_{i,b}$ . Using the terminology of linear systems this can be expressed as

$$W_b = \mathbf{L}_d(k^{n_1}), V_{i,b} = H^0(\mathcal{O}_{E_1}(k)) \text{ and } U_{i,b} = \mathbf{L}_k(m^{n_2}).$$

So over each  $b \in B$ , we have the construction that arises in diagram (\*) on page 6.

Recall that we want to calculate the dimension of the intersection in  $\bigoplus_{i=1}^{n_1} V_{i,b}$ . Restricting to  $E_{i,b}$  leaves us with the following inclusions:

Next we describe group action on it: Let  $\mathcal{G}$  be a family of groups  $G:=GL_2(\mathbb{C})$  over B defined by

$$Aut_B(f_*\mathcal{F}(0,1)\mid_{\mathcal{E}_1})\times\ldots\times Aut_B(f_*\mathcal{F}(0,1)\mid_{\mathcal{E}_{n_1}}.$$

The symmetric group  $S_{n_1}$  acts on  $\mathcal{G}$  by acting both on B and on the copies of  $GL_2$ , so that if

$$\sigma = \begin{pmatrix} 1 & 2 & \dots & n_1 \\ \sigma_1 & \sigma_2 & \dots & \sigma_{n_1} \end{pmatrix}$$

is an element of  $S_{n_1}$ , then  $(b,g) = (b_1, \ldots, b_{n_1}; g_1, \ldots, g_{n_1})$  is sent to  $\sigma(b,g) = (b_{\sigma_1}, \ldots, b_{\sigma_{n_1}}; g_{\sigma_1}, \ldots, g_{\sigma_{n_1}})$ .

The construction of bundles  $U_i$  and W and the symmetric group action induce isomorphisms

$$U_{\sigma_i,(b_1,\ldots,b_{n_1})} \cong U_{i,(b_{\sigma_1},\ldots,b_{\sigma_{n_1}})}$$
 and  $p_{\sigma_i} W_{(b_1,\ldots,b_{n_1})} \cong p_i W_{(b_{\sigma_1},\ldots,b_{\sigma_{n_1}})}$ ,

where  $p_i$  is the restriction map  $p_i: W \to V_i$ .

The aim of this construction is to prove that vector spaces  $U_i$ ,  $V_i$ , W satisfy quasi symmetric condition defined in 3. We first check condition (a): Choose

$$\sigma = \begin{pmatrix} 1 & 2 & \dots & r & r+1 & \dots & n_1 \\ 2 & 3 & \dots & r+1 & 1 & \dots & n_1 \end{pmatrix}.$$

If there exists  $(b, g) \in \mathcal{G}$  such that

$$(p_1,\ldots,p_r)W_b\cap(g_1U_{1,b}\oplus\ldots\oplus g_rU_{r,b})=0$$

then there exists an open set  $A \subset \mathcal{G}$  with the same property. Choose an element  $(b_1, \ldots, b_{n_1}; g_1, \ldots, g_{n_1})$  in the intersection of open sets  $A \cap \sigma^{-1}(A)$ . Then

$$(p_1,\ldots,p_r)W_{\sigma(b)}\cap(g_{\sigma_1}U_{1,\sigma(b)}\oplus\ldots\oplus g_{\sigma_r}U_{r,\sigma(b)})=0$$

since  $\sigma(b, g) \in A$ . But this is isomorphic to

$$(p_{\sigma_1},\ldots,p_{\sigma_r})W_b\cap(g_{\sigma_1}U_{\sigma_1,b}\oplus\ldots\oplus g_{\sigma_r}U_{\sigma_r,b})=$$

$$(p_2,\ldots,p_{r+1})W_b\cap (g_2U_{2,b}\oplus\ldots\oplus g_{r+1}U_{r+1,b})=0.$$

The obvious inclusion

$$(p_1, \dots, p_{r+1})W_b \cap (g_1U_{1,b} \oplus \dots \oplus g_{r+1}U_{r+1,b}) \subseteq ((p_1, \dots, p_r)W_b \cap (g_1U_{1,b} \oplus \dots \oplus g_rU_{r,b})) \oplus ((p_2, \dots, p_{r+1})W_b \cap (g_2U_{2,b} \oplus \dots \oplus g_{r+1}U_{r+1,b})) = 0.$$

proves condition (a).

For condition (b) assume that there exists  $(b, g) \in \mathcal{G}$  for which

$$(p_1,\ldots,p_r)W_b\cap(g_1U_{1,b}\oplus\ldots\oplus g_rU_{r,b})$$

is transversal and nonzero, and

$$p_{r+1}W' \cap g_{r+1}U_{r+1,b} = 0.$$

Recall that W' is defined to be

$$(p_1, \ldots, p_r)^{-1}[p_1, \ldots, p_r W_b \cap (g_1 U_{1,b} \oplus \ldots \oplus g_r U_{r,b})].$$

Then there exists an open set  $C \subseteq \mathcal{G}$  with the same property.  $\sigma^{-1}(C)$  is also open. For every element  $(b_1, \ldots, b_{n_1}; g_1, \ldots, g_{n_1})$  in the intersection  $C \cap \sigma^{-1}(C)$  we get

$$p_{r+1}W'' \cap g_{\sigma_{r+1}}U_{r+1,\sigma(b)} = 0,$$

where

$$W'' = (p_1, \ldots, p_r)^{-1} [p_1, \ldots, p_r W_{\sigma(b)} \cap (g_{\sigma_1} U_{1,\sigma(b)} \oplus \ldots \oplus g_{\sigma_r} U_{r,\sigma(b)})].$$

This is true since  $\sigma(b, g) \in \mathcal{C}$ . Using above isomorphisms we get

$$W'' \cong (p_{\sigma_1}, \ldots, p_{\sigma_r})^{-1}[p_{\sigma_1}, \ldots, p_{\sigma_r}W_b \cap (g_{\sigma_1}U_{\sigma_1,b} \oplus \ldots \oplus g_{\sigma_r}U_{\sigma_r,b})],$$

which we denote by  $\ddot{W}$ . Clearly  $p_{r+1}W''\cong p_{\sigma_{r+1}}\ddot{W}$  and  $g_{\sigma_{r+1}}U_{r+1,\sigma(b)}\cong g_{\sigma_{r+1}}U_{\sigma_{r+1},b}$  This implies

$$p_{\sigma_{r+1}} \ddot{W} \cap g_{\sigma_{r+1}} U_{\sigma_{r+1},b} \cong p_{r+1} W'' \cap g_{\sigma_{r+1}} U_{r+1,\sigma(b)} = 0.$$

Finally take  $(b, g) \in \mathcal{C} \cap \sigma^{(1)}(\mathcal{C}) \cap \ldots \cap \sigma^{(r)}(\mathcal{C})$  where

$$\sigma^{(i)} = \begin{pmatrix} 1 & 2 & \dots & i & \dots & r+1 & \dots & n_1 \\ 1 & 2 & \dots & r+1 & \dots & i & \dots & n_1 \end{pmatrix}.$$

For every element

$$w \in W_b \cap (g_1U_{1,b} \oplus \ldots \oplus g_{r+1}U_{r+1,b})$$

we get  $p_{r+1}w \in p_{r+1}W' \cap g_{r+1}U_{r+1,b}$  which is by assumption 0. On the other hand  $p_iw \in p_i\ddot{W} \cap g_iU_{i,b}$  which is again 0, since  $\sigma^{(i)} \in C$ . We proved that

$$w = (p_1, \ldots, p_{r+1})w = 0.$$

This verifies condition (b) in the definition of quasi-symmetry.
