

## A NOTE ON CONNECTED GRAPHS

DĂNUȚ MARCU

In this paper, we show that every connected graph  $G$  of order  $p \gg 3$  has two distinct vertices  $u$  and  $v$ , such that  $G - u$ ,  $G - v$  and  $G - u - v$  are connected.

### Introduction.

The terminology and notation, used in this paper, are those of [2]. A *digraph*  $D$  is a finite nonempty set  $V$  together with an irreflexive relation  $E$  on  $V$ . We call each element of  $V$  a *vertex*, and each ordered pair of  $E$  an *arc*. Furthermore, the cardinality of  $V$  is termed the *order* of  $D$ .

A finite sequence of vertices and arcs  $u_0, e_0, u_1, \dots, e_{n-1}, u_n$  is called an  $u_0 - u_n$  *semiwalk* in  $D$ , if for each  $i, 0 \ll i \ll n - 1$ , either  $e_i = (u_i, u_{i+1})$  or  $e_i = (u_{i+1}, u_i)$ . If for each pair of vertices  $u$  and  $v$  there exists an  $u - v$  semiwalk in  $D$ , we say that  $D$  is *weakly connected* or *weak*. In addition, if  $w$  is a vertex of  $D$  for which  $D - w$  is not weak, then  $w$  is called a *cut-vertex* of  $D$ .

An  $u_0 - u_n$  *walk* in  $D$  is a semiwalk  $u_0, e_0, u_1, \dots, e_{n-1}, u_n$ , in which  $e_i = (u_i, u_{i+1})$  for  $i = 0, 1, \dots, n - 1$ . An  $u_0 - u_n$  walk is *closed*, if  $u_0 = u_n$ , and *spanning*, if it contains every vertex of  $D$ . Furthermore, if for each pair of vertices  $u$  and  $v$ ,  $D$  contains either an  $u - v$  walk or a  $v - u$  walk, then  $D$  is called *unilateral*, while if  $D$  contains both an  $u - v$  walk and a  $v - u$  walk,  $D$  is *strong*.

**Main result.**

We shall need the following known result which characterizes unilateral and strong digraphs [2]. Since our proof is instructive and believed to be new, we include it here.

**Lemma 1.** *A digraph is unilateral if and only if it has a spanning walk, and strong if and only if it has a closed spanning walk.*

*Proof.* Clearly, if a digraph has a spanning walk, then it is unilateral. It is equally clear that a digraph with a closed spanning walk is strong.

Suppose that  $D$  is an unilateral digraph and let  $W$  be an walk in  $D$  containing the maximum number of distinct vertices. If  $W$  is not spanning, then let  $v$  be a vertex not belonging to  $W$ . By our choice of  $W$ , there can be neither an walk from  $v$  to the first vertex of  $W$  nor an walk from the last vertex of  $W$  to  $v$ . Let  $u$  be the last vertex of  $W$  from which there exists an walk to  $v$ . Let  $W_1$  be an  $u - v$  walk. By our choice of  $u$ , since  $D$  is unilateral, there must be an walk, say  $W_2$ , from  $v$  to the vertex, say  $w$ , which follows  $u$  on  $W$ . But now, we can insert  $W_1 U W_2$  between  $u$  and  $w$  on  $W$  to obtain an walk using at least one vertex, namely  $v$ , not belonging to  $W$ . This contradicts our choice of  $W$ . Thus,  $W$  must be spanning. If  $D$  is a strong digraph, then it is also unilateral. Hence, it contains a spanning walk, say  $W$ , beginning and ending at say  $u$  and  $v$ , respectively. Since  $D$  is strong, there exists a  $v - u$  walk, say  $W'$ , in  $D$ . Then,  $W$  followed by  $W'$  is a closed spanning walk.  $\square$

**Lemma 2.** *If  $D$  is an unilateral digraph of order  $p \gg 3$ , then  $D$  has two distinct vertices  $u$  and  $v$ , such that  $D - u$ ,  $D - v$  and  $D - u - v$  are unilateral.*

*Proof.* Let  $D$  be an unilateral digraph of order  $p \gg 3$ , and let  $W$  be a shortest spanning walk of  $D$ . Further, let  $u$  and  $v$  be the first and last vertices, respectively, of  $W$ . We note that  $u$  appears exactly once on  $W$  (otherwise,  $D$  is spanned by the shorter walk which starts at the second vertex of  $W$  and follows the remainder of  $W$  to  $v$ ). Also,  $v$  appears but once on  $W$  (otherwise,  $D$  is spanned by the shorter walk which follows  $W$  from  $u$  and ends at the next to last vertex of  $W$ ). Clearly then,  $D - u$ ,  $D - v$  and  $D - u - v$  have spanning walks which are subwalks of  $W$ . Hence, by Lemma 1, each is unilateral.  $\square$

It is well-known that every connected graph has a spanning walk [2]. Thus, the proof of Lemma 2, when slightly modified, establishes the well-known result that every nontrivial connected graph has at least two non-cut-vertices. In fact, it gives us the following

**Theorem.** *Every connected graph  $G$  of order  $p \gg 3$  has two distinct vertices  $u$  and  $v$ , such that  $G - u$ ,  $G - v$  and  $G - u - v$  are connected.  $\square$*

Let us conclude with a result due to Geller [1], pag. 15, which is an immediate corollary of Lemma 2.

**Corollary.** *If  $D$  is a strong digraph of order  $p \gg 4$  which has no cut-vertex, then  $D$  has at least two distinct vertices  $u$  and  $v$ , such that  $D - u$  and  $D - v$  are unilateral.  $\square$*
